

A slab leak is one of those plumbing problems that likes to practice its villain laugh in private. It hides under concrete, whispers through your water meter, warms a suspicious patch of flooring, and then quietly sends the water bill into orbit. By the time many homeowners notice something is wrong, the leak has already been hosting a tiny underground pool party beneath the house.

The good news is that slab leaks are repairable. The less comforting news is that guessing rarely helps. A slab leak needs careful diagnosis, the right repair method, and a plumber who owns more than a flashlight and a hopeful attitude. If you suspect one, speed matters, but so does accuracy. Breaking through a slab in the wrong place is an expensive way to learn about humility.

Let's walk through what slab leaks are, how they happen, what signs to watch for, and how professionals approach slab leak repair without turning your home into an archaeological dig site.

What is a slab leak, really?

Many homes are built on a concrete slab foundation. Instead of having a basement or crawl space below the house, the plumbing lines often run under or through the slab. These lines may carry hot water, cold water, or sometimes wastewater, depending on the home's design and age.

A slab leak happens when one of those pipes begins leaking beneath the concrete. Sometimes the leak is a fine spray from a pinhole. Sometimes it is a cracked pipe or a failed joint. Either way, water escapes where it should not, and concrete does not politely raise its hand to report the problem.

The term "slab leak" usually refers to pressurized water lines, because those leaks tend to reveal themselves faster. Drain line leaks under a slab can also occur, but they often behave differently. A supply line leak may run constantly because the pipe is always under pressure. A drain leak may only show symptoms when fixtures are used. Both can cause damage. Both deserve attention. Neither improves after being ignored, despite what your inner procrastinator may suggest.

Why slab leaks are so tricky

A dripping faucet makes itself known. A leaking toilet flapper rattles through the sound of running water. A slab leak, on the other hand, hides beneath inches of concrete, flooring, cabinets, furniture, and occasionally a rug purchased specifically because "it really ties the room together."

The challenge is not just finding water. It is finding the source. Water travels along the path of least resistance, which may be through cracks, expansion joints, soil channels, or under flooring. The wet spot in your hallway might not sit directly above the leak. A warm patch in the kitchen could come from a hot water line several feet away. Plumbing systems are logical, but leaks have a mischievous streak.

Professional leak detection uses a mix of tools and judgment. Acoustic listening equipment can pick up the sound of pressurized water escaping a pipe. Thermal imaging may reveal heat patterns from a hot water leak. Pressure testing can isolate sections of plumbing. Tracer gas, moisture meters, and camera inspections may also play a role. The equipment matters, but experience matters just as much. A seasoned local plumber knows when the obvious answer is too obvious, which is how floors avoid unnecessary jackhammer therapy.

The signs your slab may be leaking

Some slab leaks announce themselves like a marching band. Others show up as a few odd clues that are easy to blame on weather, pets, kids, or “old house stuff.” The sooner you recognize the pattern, the better your odds of limiting damage.

Common signs include:

HVAC contractor

1. A water bill that rises sharply without a clear reason.
2. The sound of running water when all fixtures are off.
3. Warm or damp spots on floors, especially over concrete.
4. Cracks in flooring, baseboards, walls, or the slab itself.
5. Low water pressure, mildew odors, or unexplained moisture.

The water bill clue deserves special attention. A small pressurized leak can waste hundreds or even thousands of gallons over a billing cycle. If your usage jumps and nobody has filled a pool, hosted a car wash, or started farming rice in the backyard, investigate.

Warm floor spots are another classic symptom, particularly with hot water line leaks. A warm tile floor in winter sounds charming until you remember you did not install radiant heating. If one area is noticeably warmer than the surrounding floor and your water heater seems to run more than usual, that is not your house being cozy. That is your plumbing sending a memo.

Damp flooring is more obvious, but not always immediate. Tile may hide moisture longer than carpet or laminate. Vinyl flooring may bubble. Wood may cup or warp. Carpet padding may hold water until odor arrives, wearing a little mildew tuxedo and ruining everyone’s afternoon.

Cracks can be more complicated. Homes settle. Concrete cracks. Drywall cracks. Not every crack means a slab leak. But if new cracks appear along with moisture, warm flooring, or higher water bills, the evidence starts looking less like coincidence and more like a pipe with commitment issues.

A quick home check before you call

There are a few safe observations homeowners can make before calling for leak repair. These checks do not replace professional diagnosis, but they can help you describe the situation clearly and avoid chasing ghosts.

First, turn off every water-using fixture in the house. Make sure the washing machine, dishwasher, ice maker, irrigation system, and hose bibs are not running. Then look at the water meter. Many meters have a small leak indicator, often a triangle or star-shaped dial. If it moves while everything is off, water is still flowing somewhere.

Next, shut off the main water valve to the house, if you can do so safely and know where it is. If the meter stops moving after the main valve is closed, the leak is likely on the house side of the system. If the meter continues moving, the leak may be between the meter and the shutoff, or the valve may not fully close. That distinction helps the plumber narrow the hunt.

Pay attention to your water heater too. If it cycles frequently when no one is using hot water, a hot line slab leak may be bleeding heat continuously. On gas units, you may hear the burner kick on more than usual. On electric units, the utility bill may offer its own painful commentary.

One caution: do not start removing flooring, drilling concrete, or pouring chemical sealers into the system because a neighbor’s cousin swears it worked once. Some shortcuts create more damage than the original leak.

Your slab does not need a science experiment.

What causes slab leaks?

Slab leaks can happen in newer homes, older homes, small homes, large homes, fancy homes, and homes with suspiciously confident DIY renovations. Still, certain causes show up again and again in the field.

Pipe corrosion is a major culprit. Copper pipes can develop pinhole leaks due to water chemistry, electrical grounding issues, soil conditions, or contact with other materials. If water is aggressive, meaning it has characteristics that encourage corrosion, the pipe may slowly thin from the inside. If the pipe exterior reacts with soil or concrete conditions, corrosion may work from the outside. Either way, the pipe loses the argument.

Abrasion is another common cause. Pipes expand and contract as hot water flows through them. If a pipe rubs against concrete, rebar, gravel, or another hard surface over many years, friction can wear down the pipe wall. It is not dramatic. It is more like a slow-motion sandpaper problem. Eventually, the metal gives up.

Poor installation can set the stage for failure. Kinked lines, poorly sleeved penetrations, bad solder joints, excessive tension, or pipes laid directly against sharp materials can all shorten pipe life. Most plumbing does not fail because one thing went wrong. It fails because one thing went wrong for a very long time.

Soil movement also plays a role. Expansive clay soils swell when wet and shrink when dry. Tree roots, drainage problems, seismic movement, and poor compaction can shift soil beneath the slab. When the ground moves, pipes may bend, stretch, or crack. Concrete is tough, but it is not magic. The plumbing underneath must survive the movement too.

Water pressure can make everything worse. High pressure stresses pipes, fixtures, valves, and water heaters. Many homes perform best around 50 to 70 psi, though acceptable ranges vary by plumbing code and system design. Once pressure climbs too high, small weaknesses become expensive events. A pressure reducing valve can help, but only if it is installed, adjusted, and functioning. Like many humble devices, it does its best work when nobody is thinking about it.

Why you should not ignore a slab leak

Ignoring a slab leak is like ignoring smoke from the toaster because the bread has not burst into flames yet. Maybe you get lucky. More likely, the problem spreads while you enjoy a false sense of thrift.

Water beneath a slab can erode soil, leaving voids under the foundation. Over time, that can contribute to settlement or cracking. It can damage flooring, cabinets, trim, and drywall. Moisture can create conditions for mold growth, especially where water migrates into walls or under flooring materials. Hot water leaks also waste energy because your water heater keeps replacing the heat being lost below the house.

There is also the simple matter of cost. A leak caught early may be isolated and repaired with limited disruption. A leak ignored for months may involve water mitigation, flooring replacement, mold remediation, foundation evaluation, and a deeply unpleasant conversation with your insurance company.

Insurance coverage varies widely. **air conditioner installation** Some policies may cover sudden and accidental water damage but exclude the cost of repairing the pipe itself. Others may limit slab access, flooring replacement, or long-term seepage. If you suspect a slab leak, document what you see, take photos, save bills, and call your insurer before major demolition begins. A good plumbing company can provide findings and repair options, but coverage decisions come from the policy, not from the guy holding the pipe cutter.

How professionals find the leak

Good slab leak detection starts with listening, literally and figuratively. A technician should ask what changed, when symptoms began, whether the leak appears tied to hot water, and what parts of the home show damage. The home's age, pipe material, water pressure, and past plumbing history all matter.

Then comes testing. The plumber may isolate hot and cold lines, shut valves, monitor pressure drops, and use acoustic equipment to hear the leak. A pressurized leak often creates a distinct sound as water escapes, although flooring type, slab thickness, soil saturation, and pipe depth affect how clearly it can be heard. Thermal imaging may show heat migration from a hot water line, though it does not "see through concrete" in the superhero sense. It reads surface temperatures. Useful, yes. Magic, no.

Some cases are straightforward. The leak is loud, the floor is warm, the pressure test confirms the line, and the repair location becomes clear. Other cases are more stubborn. Multiple leaks, recirculation systems, manifold plumbing, remodels, or poorly mapped lines can complicate the search. Homes do not always match the original plans, especially after twenty years and three owners with different levels of enthusiasm for "weekend projects."

A careful plumber will explain the confidence level before opening the slab. There is always some judgment involved, but the goal is to reduce uncertainty as much as possible. If someone walks in, glances at a wet spot, and says they know exactly where to break concrete without testing, feel free to clutch your flooring protectively.

Slab leak repair options

There is no single best repair for every slab leak. The right choice depends on the pipe material, leak location, home layout, number of leaks, condition of the plumbing system, budget, flooring, and how much disruption the homeowner can tolerate. A reputable plumbing contractor will discuss options rather than acting as if the jackhammer is the only instrument in the orchestra.

Direct access repair

Direct access means opening the floor and slab at or near the leak, repairing the damaged pipe, then restoring the concrete and flooring. When the leak location is highly certain and the pipe is otherwise in good condition, this can be a practical option. It often costs less than rerouting a long line, and it preserves the existing plumbing layout.

The downside is disruption. Concrete cutting creates dust and noise, even with good containment. Flooring must be removed and later replaced. If the leak is under cabinets, a shower, a kitchen island, or that one imported tile discontinued during the previous presidential administration, direct access becomes less attractive.

There is also a strategic concern. If one section of pipe failed because the whole under-slab system is aging or corroding, patching one leak may only buy time until the next leak appears. Sometimes that is still the right decision. Not everyone is ready for a larger repipe, and not every leak means doom. But the condition of the system should be part of the conversation.

Rerouting the line

Rerouting abandons the leaking under-slab section and runs a new line through walls, attic space, ceilings, or other accessible paths. For many homes, especially where the leaking line is hard to reach or the slab area is finished with expensive flooring, rerouting is cleaner than excavation.

This method avoids opening the slab in many cases. It also removes the failed under-slab section from service. The trade-off is that walls or ceilings may need access openings, and the new route must be protected from heat,

freezing, abrasion, and future damage. In hot climates, attic water lines need thoughtful insulation and routing. Nobody wants cold water arriving at the tap preheated like it spent the afternoon sunbathing.

Rerouting takes planning. The shortest path is not always the best path. A line should be serviceable, code-compliant, and protected. If your plumber considers HVAC ducts, framing, electrical wiring, and insulation before proposing a route, that is a good sign. Plumbing does not live alone in the house. It shares space with heating installation equipment, air handlers, electrical lines, and all the other mechanical clutter that keeps modern life civilized.

Repiping

If a home has repeated slab leaks, widespread corrosion, or outdated pipe materials, a partial or whole-home repipe may be the most sensible long-term solution. Repiping is a larger project, but it can end the cycle of chasing leaks one at a time.

The material choice depends on local code, water conditions, budget, and homeowner preference. PEX is common in many regions because it is flexible, efficient to install, and resistant to certain corrosion issues that affect metal piping. Copper remains popular where conditions suit it and installation quality is high. CPVC appears in some systems, though it requires proper support and handling, especially as it ages.

Repiping sounds dramatic, and yes, it can involve wall openings, scheduling, and patching. But compared with repeated slab access, emergency calls, water damage, and nervous glances at the floor every time the water heater runs, it may be the calmer path.

Pipe lining and epoxy solutions

Some companies offer internal pipe lining or epoxy coating as a trenchless repair option. In the right circumstances, these systems can reduce demolition. They usually involve cleaning and drying the pipe, then applying a lining or coating inside. Suitability varies. Pipe size, pipe condition, leak type, water quality, local approvals, and access points all matter.

This is not a universal fix. If a pipe is crushed, severely deteriorated, improperly sloped, or part of a system with multiple weak points, lining may not be appropriate. Homeowners should ask detailed questions about warranties, drinking water approvals where applicable, service life expectations, and what happens if another section fails later. A clever solution is still only clever when it fits the problem.

What the repair process feels like from the homeowner side

Most homeowners want to know two things: how long this will take and how much chaos to expect. Fair questions. A slab leak has already been rude enough.

Detection may take a couple of hours in simple cases and longer in complicated ones. Direct access repairs may be completed in a day once the leak is found, though flooring and finish restoration can stretch the timeline. Reroutes may take a day or two for many residential lines, depending on length and access. Whole-home repipes can take several days, with additional time for drywall and paint.

Water service may need to be shut off during portions of the work. A thoughtful plumber will tell you when, for how long, and whether temporary service is possible. If the leak is severe, shutting off the water immediately may be necessary until repairs begin. That is inconvenient, but so is indoor shoreline development.

Dust control matters. Concrete cutting should involve containment, ventilation, and cleanup. Technicians should protect flooring and furniture along work paths. If water damage is present, a mitigation company may need to dry affected areas with fans and dehumidifiers. Plumbing stops the leak. Drying prevents the aftermath from becoming its own sequel.

How much does slab leak repair cost?

Costs vary too much by region and house layout to give a single honest number. A basic leak detection visit might cost a few hundred dollars in many markets, while complex diagnostics may cost more. Direct access repairs can range widely depending on flooring, slab thickness, pipe type, and restoration needs. Reroutes and repipes cost more upfront but may reduce future risk.

Several factors drive the final price:

1. How hard the leak is to locate and access.
2. Whether the repair requires slab cutting, wall openings, or ceiling access.
3. The length and complexity of rerouting, if chosen.
4. Pipe material, code requirements, permits, and inspections.
5. Water damage cleanup, flooring replacement, and finish repairs.

Be cautious with suspiciously low quotes. Sometimes they exclude detection, concrete repair, permits, drywall, flooring, or after-hours work. Other times the quote assumes the leak is exactly where everyone hopes it is, which is not a plan. Ask what is included, what is not, and what could change once the work begins.

Also be cautious with fear-based upselling. A slab leak is serious, but it does not automatically mean your entire house is moments from floating away. The best contractors explain evidence, options, and trade-offs. They do not need horror music.

Slab leaks and the rest of your home's mechanical systems

A slab leak is a plumbing issue, but it can brush up against other systems in sneaky ways. Moisture near air conditioning equipment, ductwork, or wall cavities can affect indoor air quality. If water reaches areas around an HVAC closet or air handler, the situation needs more than a mop and a brave face. Electrical components, insulation, and condensate drains may need inspection.

In some homes, homeowners first notice the problem while calling an air conditioning contractor because rooms feel humid or musty. The AC may be working fine, but hidden moisture keeps adding load to the space. Likewise, damp areas around baseboards may be blamed on condensation from air conditioning, especially in humid climates. Sometimes that is true. Sometimes the slab is leaking and the AC is merely standing nearby looking guilty.

Heating installation work can also reveal old plumbing problems. When walls, ceilings, or mechanical spaces are opened for HVAC upgrades, hidden water stains or corroded piping may appear. A company that understands both plumbing and HVAC can be useful in these moments, because the systems often occupy the same cramped spaces. Firms such as TruFinity Plumbing Heating & Cooling, for example, work across plumbing, heating, and cooling concerns, which can make coordination easier when a leak affects more than one part of the home.

That said, credentials matter more than a long list of services. Whether you call a local plumber, a leak detection specialist, or a full-service mechanical contractor, make sure the person diagnosing the slab leak has the right tools, licensing where required, and specific experience with under-slab plumbing.

Preventing future slab leaks, or at least lowering the odds

You cannot control every cause of slab leaks. Soil moves. Pipes age. Previous installers make choices you discover years later with a flashlight and a muttered insult. Still, you can reduce risk.

Water pressure is a good place to start. Have it checked periodically, especially if you notice banging pipes, frequent toilet fill valve failures, dripping relief valves, or appliances that seem to wear out early. If the home has a pressure reducing valve, it should be tested and replaced when it fails. These valves do not last forever. They age like everything else, except with less complaining and more consequences.

Water quality also matters. If corrosion is common in your area, ask about testing. pH, hardness, chlorides, and other characteristics can influence pipe longevity. Treatment is not always necessary, and bad treatment choices can create new problems, but information helps. Plumbing prefers facts over vibes.

Drainage around the foundation deserves attention too. Gutters, downspouts, grading, irrigation, and landscaping all affect soil moisture. Keeping water from pooling near the slab helps reduce soil movement and foundation stress. If one side of the house is a swamp and the other side is a desert, the slab may experience uneven movement. Houses enjoy balance. They are surprisingly zen about it.

If you have had one slab leak, ask whether the failed pipe offers clues. Was it a pinhole? A rubbed section? A bad joint? A split from movement? The answer can guide prevention. A single damaged spot from abrasion may not predict widespread failure. Multiple pinholes in aging copper may suggest a system-wide issue. Treating every leak the same is how people overspend in the wrong direction.

When it is an emergency

Not every slab leak floods the house immediately, but some deserve urgent action. If water is surfacing through floors, soaking carpet, spreading under walls, or causing electrical hazards, shut off the water and call for help. If you see foundation movement, significant cracking, or doors suddenly sticking along with leak symptoms, move quickly. If the leak is on a hot water line and the water heater runs constantly, shut off the water heater according to the manufacturer's instructions or call a professional for guidance. Running a water heater without proper water supply can damage it.

If you smell mold, see visible growth, or have health concerns, involve a qualified remediation professional. Plumbers fix pipes. Mold specialists evaluate and remediate contaminated materials. Sometimes one problem requires more than one trade, which is annoying but better than pretending the laws of biology are negotiable.

For multi-story buildings, condos, and townhomes, notify the association or property manager right away. Shared walls, common plumbing, insurance responsibilities, and access rules can complicate repairs. Waiting can turn a private leak into a neighborhood diplomatic incident.

Choosing the right plumber for slab leak repair

A slab leak is not the ideal audition space for the cheapest available stranger with a wrench. You want someone who can diagnose carefully, communicate clearly, and repair the issue with minimal unnecessary damage.

Ask how they locate slab leaks, what equipment they use, and whether they perform pressure testing. Ask whether they offer direct repair, rerouting, and repiping, or whether they only recommend one method for every house. Ask about permits and inspections where required. Ask who handles concrete patching, drywall, flooring, and water damage drying. A professional answer does not have to be fancy. It just has to be clear.

Local experience helps. Soil conditions, common pipe materials, water chemistry, and building styles vary by region. A local plumber who has repaired slab leaks in your neighborhood may recognize patterns faster than someone learning on your dime. If your home has integrated mechanical systems, or if the leak affects an HVAC area, a contractor familiar with plumbing and heating and cooling systems can reduce coordination headaches.

Reviews can help, but read them with an eye for details. "Great service" is nice. "They found a hot water slab leak under the hallway, rerouted through the attic, protected the floors, and explained the pressure test" is more useful. Specifics beat applause.

The practical path forward

If you suspect a slab leak, start with calm observation. Check the meter. Listen for running water. Note warm spots, damp flooring, odors, and changes in water pressure. Then call a qualified professional before the problem earns a larger budget.

Slab leak repair is part science, part craftsmanship, and part detective work. The best approach may be a small direct repair, a smart reroute, or a broader repipe. The answer depends on the house, the pipe, the leak, and your tolerance for risk and disruption.

What you should not do is ignore it and hope the concrete changes its mind. Concrete is stubborn. Water is patient. Together, they are expensive. A well-handled repair stops the leak, protects the structure, and lets you return to more enjoyable household mysteries, like why the air conditioning only makes that noise when guests are over, or how one family can own seventeen unmatched container lids and no matching containers.

TruFinity Plumbing Heating & Cooling – Local Business Details

Kelowna

Name: TruFinity Plumbing Heating & Cooling

Address: 470 Neave Ct #104, Kelowna, BC V1V 2M2

Phone: (250) 800-3811

Website: <https://www.trufinity.ca/>

Email: service@trufinity.ca

Hours: Monday–Sunday: 24/7 emergency service; regular office hours

TruFinity Plumbing Heating & Cooling provides plumbing, heating, cooling, drain, sewer, water quality, and indoor air quality services for homes and businesses across the Okanagan and nearby service areas.

The team serves customers through local pages for Kelowna, West Kelowna, Vernon, Penticton, and Kamloops, helping property owners find support close to their community.

For plumbing needs, TruFinity can help with repairs, fixture work, water heaters, gasfitting, inspections, and related home-service projects.

For heating and cooling, the company lists furnace, boiler, heat pump, AC, mini-split, thermostat, HVAC repair, installation, and maintenance services.

Customers looking for local service can use the Google Business Profile links for Kelowna, West Kelowna, Vernon, Penticton, and Kamloops to find the nearest TruFinity listing.

The brand's public contact information includes service@trufinity.ca and the main website at <https://www.trufinity.ca/>.

Kelowna customers can contact the local page at (250) 800-3811, while West Kelowna, Vernon, and Penticton each list dedicated local phone numbers.

TruFinity's website highlights 24/7 emergency service availability for urgent plumbing and HVAC issues, with regular office hours requiring confirmation if needed.

For the most accurate location details, customers should check the relevant map/listing URL or contact TruFinity directly before visiting a service address.

Popular Questions About TruFinity Plumbing Heating & Cooling

What services does TruFinity Plumbing Heating & Cooling provide?

TruFinity lists plumbing, heating, cooling, drain and sewer, water and air quality, and construction-related services. Common services include plumbing repairs, water heaters, gasfitting, furnace services, heat pumps, AC services, mini-splits, drain cleaning, sewer line services, and indoor air quality support.

Where does TruFinity Plumbing Heating & Cooling provide service?

TruFinity lists service-area pages for Kelowna, West Kelowna, Vernon, Penticton, and Kamloops. Customers should use the nearest location page or Google Business Profile link to confirm the best local contact option.

Does TruFinity handle both plumbing and HVAC?

Yes. TruFinity's official site lists plumbing as well as heating and cooling services, including furnace, boiler, heat pump, AC, mini-split, and thermostat services.

Does TruFinity offer emergency service?

The website states that TruFinity is available around the clock for urgent plumbing and HVAC issues. Regular office hours were not clearly listed for every location and should be confirmed directly with the business.

What is the Kelowna TruFinity address?

The Kelowna location is listed as 470 Neave Ct #104, Kelowna, BC V1V 2M2. The Kelowna phone listed on the service-area page is [\(250\) 800-3811](tel:2508003811).

What is the West Kelowna TruFinity address?

The West Kelowna location is listed as 615 Keefe Rd, West Kelowna, BC V1Z 1C6. The West Kelowna phone listed on the service-area page is [\(778\) 721-8344](tel:7787218344).

What is the Vernon TruFinity address?

The Vernon location is listed as 2907 32 St #101, Vernon, BC V1T 5M2. The Vernon phone listed on the service-area page is [\(778\) 721-8375](tel:7787218375).

What is the Penticton TruFinity address?

The Penticton location is listed as 208 Ellis St #102, Penticton, BC V2A 4L6. The Penticton phone listed on the service-area page is [\(778\) 721-8308](tel:7787218308).

What is the best way to contact TruFinity Plumbing Heating & Cooling?

Customers can call [\(250\) 707-8285](tel:2507078285), email service@trufinity.ca, or visit <https://www.trufinity.ca/>. Social profiles include <https://www.facebook.com/TruFinityPHC/> <https://www.instagram.com/trufinityphc/> <https://www.linkedin.com/company/trufinityphc/> and <https://www.youtube.com/@TruFinityphc/>.

Landmarks Near Kelowna, West Kelowna, Vernon, Penticton & Kamloops

Knox Mountain Park – Kelowna

A well-known Kelowna landmark near central neighbourhoods and lakeside routes.

Orchard Park Shopping Centre – Kelowna

A major Kelowna shopping area close to many residential and commercial properties.

UBC Okanagan – Kelowna

A major campus area in north Kelowna near residential developments, rentals, and service properties.

Downtown Kelowna and Bernard Avenue – Kelowna

Downtown Kelowna includes shops, restaurants, offices, apartments, and nearby homes that may need plumbing or HVAC service.

Rose Valley Regional Park – West Kelowna

A recognizable West Kelowna area near hillside neighbourhoods.

Gellatly Bay Waterfront – West Kelowna

A lakeside West Kelowna landmark near homes, townhomes, and small businesses.

Polson Park – Vernon

A central Vernon landmark near neighbourhoods and local businesses.

Village Green Shopping Centre – Vernon

A practical Vernon reference point for residents and commercial properties.

Okanagan Lake Park – Penticton

A downtown Penticton waterfront landmark close to homes, rentals, restaurants, and shops.

Skaha Lake Park – Penticton

A major south Penticton landmark near residential areas and seasonal properties.

Riverside Park – Kamloops

A central Kamloops landmark near downtown homes and commercial properties.

Aberdeen Mall – Kamloops

A major Kamloops reference point near residential and commercial areas.
